

TRUSTMRR · 1,000-COMPANY DATASET

TrustMRR Market Intelligence

Exploratory Data Analysis and Strategic Insights on the Revenue,
Growth, and Valuation Signals of 1,000 Indie SaaS and App Businesses

Prepared by Business Analytics & Strategy Team

Confidential — For Internal Discussion

Executive Summary

A power-law market where a small elite captures most of the value

1,000

companies tracked
across 65 countries

\$15.6M

combined monthly
revenue in scope

83.7%

of all revenue held by
just the top 10% of firms

0.02

correlation between
followers and revenue

- **Extreme revenue concentration.** The top 1% of companies (10 of 1,000) generate 49.6% of all tracked monthly revenue — this is a power-law market, not a normal distribution.
- **Audience size is a vanity metric here.** X/social followers show virtually no relationship to revenue ($r = 0.02$); domain authority and B2B positioning matter far more.
- **B2B monetizes ~4x better than B2C.** Average B2B revenue is \$22,638/mo versus \$5,723/mo for B2C, despite B2C having 57% more companies in the dataset.
- **Valuation multiples are noisy.** The average asking multiple (7.8x) is more than 3x the median (2.3x) — a handful of near-zero-revenue listings distort the average.

Dataset Overview

What the data represents and how complete it is

The dataset is a snapshot from TrustMRR — a public leaderboard of self-reported, API-verified revenue for bootstrapped SaaS products, mobile apps, and online businesses. Each row is one company; each column is a business, financial, or firmographic attribute at a point in time.

Variable group	Examples	Type
Identity & firmographics	startup_name, country, category, audience_type	Categorical / Text
Revenue & subscriptions	revenue_30d/3m/12m/all-time, mrr_usd, active_subscriptions	Numerical
Growth signals	revenue_growth_30d_pct, mrr_growth_30d_pct	Numerical
Marketing & traffic	x_followers, visitors_30d, revenue_per_visitor_usd, domain_rating	Numerical
Deal / M&A signals	on_sale, asking_price_usd, revenue_multiple	Binary / Numerical
Qualitative descriptors	value_proposition, problem_solved, pricing_model	Text

Sample & Data Quality

1,000 companies · 29 variables · 0 duplicate rows

asking_price_usd / revenue_multiple	73.9%
revenue_per_visitor_usd	85.8%
visitors_30d	82.2%
category	27.4%
country	24.1%

Anonymized listings: 130 companies (13.0%) are posted as “Stealth Company” or “Hidden Business,” yet still contribute ~27% of total revenue.

Descriptive Statistics

Every core revenue metric is right-skewed — the mean is not the typical company

Metric	Median	Mean	Std Dev	P90	Max
Revenue (30d, \$)	400	15,596	108,136	24,588	2,844,652
MRR (\$)	282	13,472	118,987	23,369	3,569,654
Revenue (12m, \$)	3,069	133,750	968,978	215,591	25,017,876
Active subscriptions	16	501	3,561	769	101,590
X followers	67	4,070	26,300	3,762	365,992
Domain rating (0-100)	10	16.7	18.5	45.7	89

Interpretation: For every core metric, the mean sits far above the median (e.g., mean 30-day revenue of \$15,596 vs. a median of just \$400) — a signature of a right-skewed, power-law distribution. Reporting means alone would badly overstate the typical company's performance; medians and percentile bands are the more honest benchmark for this population.

Distribution Analysis

Revenue concentration follows a textbook Pareto curve

Reading the Curve

- The top 10 companies alone (1% of the dataset) generate almost half of all tracked monthly revenue.
- The top 200 companies (20%) account for 94% of revenue — the other 800 firms share the remaining 6%.
- This is consistent with typical marketplace and creator-economy dynamics: a small number of breakout winners, a long tail of early-stage or side-project revenue.
- Implication: any 'average company' framing is misleading. Segment analysis, benchmarking, and BD prioritization should be tier-based, not average-based.

Customer Segmentation

B2B commands a clear revenue premium; a handful of categories dominate

Average 30-Day Revenue by Audience Type

Top Categories by Total 30-Day Revenue (\$)

What the Segments Tell Us

B2B ≈ 4x B2C on average revenue.

\$22,638/mo vs. \$5,723/mo — despite B2C having 57% more listed companies. Business buyers pay more per seat/account than consumers.

AI is the largest category by count (197 firms) but wildly uneven.

Median AI revenue is just \$503/mo against a mean of \$11,963 — a few breakout AI products carry the category.

Marketing tools monetize best per company.

42 firms average \$31,364/mo — nearly 3x the AI category average — suggesting tighter product-market fit and willingness to pay for measurable ROI tools.

'Both' (B2B+B2C hybrid) audiences underperform pure B2B.

At \$4,195/mo average, hybrid positioning may signal unclear ICP focus rather than market expansion.

Correlation Analysis

What actually moves with revenue — and what doesn't

	Revenue 30d	MRR	Active Subs	X Followers	Domain Rating	Asking Price	Growth %
Revenue 30d	1.00	0.87	0.80	0.02	0.28	0.85	0.00
MRR	0.87	1.00	0.91	0.02	0.21	0.81	-0.01
Active Subs	0.80	0.91	1.00	0.01	0.20	0.33	-0.01
X Followers	0.02	0.02	0.01	1.00	0.20	0.24	0.00
Domain Rating	0.28	0.21	0.20	0.20	1.00	0.22	-0.03
Asking Price	0.85	0.81	0.33	0.24	0.22	1.00	-0.04
Growth %	0.00	-0.01	-0.01	0.00	-0.03	-0.04	1.00

Key reads: (1) X followers correlate with almost nothing ($r \leq 0.24$ everywhere) — social reach is not a revenue driver on this platform. (2) Asking price tracks revenue closely ($r = 0.85$) — sellers price mainly off trailing revenue, not growth. (3) 30-day revenue growth is essentially uncorrelated with size, multiple, or followers — growth is idiosyncratic, not structural.

Key Trends

Platform concentration extends beyond revenue — into geography and payments

Revenue Share by Payment Provider

Stripe processes 63.6% of companies but 86.7% of dollars — its merchants skew toward larger, higher-revenue businesses than RevenueCat's largely mobile/app-store base.

Revenue Share by Country (Top 5)

The US alone accounts for 63.1% of all tracked revenue from just 25.8% of companies — US-based listings monetize roughly 4.5x more per company than the global average.

Deep Insights

Consultant-level reads beyond the summary statistics

01

Followers are theater, not fundamentals.

A social following of 100,000 correlates with revenue no better than one of 100 ($r = 0.02$ overall). Any acquisition or scoring model that weights follower count as a quality signal on this platform is measuring the wrong thing.

02

The valuation market is inefficient today.

Revenue multiple shows no relationship to growth rate ($r = -0.04$). Buyers are not yet paying a systematic premium for faster-growing businesses — a mispricing that disciplined buyers could arbitrage.

03

Confidentiality doesn't mean small.

The 130 anonymized 'Stealth' listings collectively hold roughly 27% of total tracked revenue — larger, more successful sellers appear just as likely to mask identity as smaller ones, likely for competitive reasons.

04

Category size and category quality diverge.

AI is the most populous category (197 firms) but Marketing tools generate ~3x more revenue per company on average — a smaller, tighter niche can out-monetize a crowded, hyped one.

Problems Identified

Data quality issues that could distort downstream analysis

Outlier-driven multiples

The average revenue multiple (7.8x) is inflated by listings with near-zero trailing revenue posting multiples above 100x (max 326.8x) — a valuation floor is needed before averaging.

Sparse funnel data

visitors_30d and revenue_per_visitor_usd are missing for 82% and 86% of companies respectively, making conversion-rate or CAC-efficiency analysis unreliable at the full-dataset level.

Duplicate listing

'Draft AI' appears twice with identical MRR, followers, and revenue figures under two different domains (getdraft.io / getdraft.app) — a rollup that doesn't dedupe will double-count it.

Placeholder / redacted text

57+ rows contain literal placeholder strings such as 'PRICING_NOT_FOUND' or '[Private metric reference available after login.]' in text fields — these should be treated as missing, not as real content, in any NLP or theming pass.

Optional self-tagging gaps

category (27%), country (24%), and audience_type (29%) are all missing at rates high enough that segment-level totals in this deck should be read as 'among tagged companies,' not as the full population.

Recommendations

Prioritized by expected impact on decision quality

HIGH

Benchmark and price off medians, not means.

Use median revenue multiple (2.3x) and median revenue (\$400/mo) as the default reference points; reserve means for total-market sizing only.

HIGH

Apply a minimum-revenue floor before computing valuation comps.

Exclude or flag listings under a set MRR threshold (e.g., \$500) from multiple-based benchmarking to remove the outliers driving the 7.8x vs. 2.3x gap.

HIGH

Prioritize BD, partnerships, and support resources on the top decile.

The top 10% of companies drive 83.7% of visible revenue — a tiered coverage model will outperform equal-weighted outreach.

MEDIUM

Drop follower count from any quality or lead-scoring model.

Replace it with domain rating and audience-type (B2B vs. B2C) flags, which carry meaningfully more signal ($r = 0.28$ and a ~4x revenue gap respectively).

MEDIUM

Investigate payment-processor concentration risk.

86.7% of revenue flows through a single processor (Stripe); assess resilience and consider surfacing multi-processor adoption as a stability signal.

LOW

Improve traffic/funnel data capture and de-duplicate listings.

Close the 82-86% gap in visitor and conversion data, and add a domain/metric fingerprint check to catch duplicate listings like 'Draft AI' before publication.

Conclusion

This dataset paints a consistent picture: **TrustMRR is a power-law market.** A small elite of companies — disproportionately US-based, B2B, Stripe-processed — captures most of the revenue, while the broad base of listed businesses earns modestly. Popularity metrics like social following carry almost no predictive weight; fundamentals like domain authority, audience type, and category fit matter far more.

Next Steps

- 1 Rebuild valuation benchmarks on median, outlier-floored multiples
- 2 Stand up a tiered coverage model around the top revenue decile
- 3 Replace follower-based scoring with domain-rating and audience-type signals
- 4 Close funnel-data gaps and de-duplicate listings before the next reporting cycle

Thank you
