

TrustMRR 1,000 – What the Numbers Are Really Saying

This consultant read walks the dataset scene by scene. Across 1,000 businesses the story repeats: a handful of winners dominate revenue and growth while the majority are tiny, flat, or inactive. Below we move through eight scenes that reveal how averages mislead, who's for sale, how prices behave, and what categories and countries actually mean.

Scene 1 – Concentration at the Top

The dataset of 1,000 businesses is highly concentrated. The top 10 businesses capture 48% of every dollar of monthly recurring revenue (MRR). Expanding to the top 50 accounts for 71% of MRR. One business – Stan – alone earns more than the bottom several hundred combined. This is not a marketplace of many similar firms but a few breakout winners sitting atop a long thin tail.

Scene 2 – The Typical Business Is Tiny

Remove the giants and the median business earns only \$282/month in recurring revenue. Nearly 1 in 5 businesses (197) report \$0 recurring revenue, many with no revenue in the last 30 days. This dataset reads like a builder ecosystem—idea-stage, side projects, or pre-traction ventures—so modest gains (a few hundred dollars/month) can already be ahead of most peers.

Median Reality

\$282/month for the company in the middle of the pack.

Zero Revenue

197 businesses at \$0 recurring revenue – many inactive in last 30 days.

Scene 3 – Headline Growth vs. Typical Growth

The headline average MRR growth for the last 30 days is 33% – a flattering metric driven by extreme outliers (one business grew nearly 13,000% in a month). The typical business saw 0% growth; 69% of businesses were flat or shrinking. Quoting the 33% average therefore misrepresents ecosystem health – it describes a mirage created by a few spikes, not the common experience.

The honest baseline is the median: most companies showed no forward progress last month.

Scene 4 – Who Is Selling?

262 businesses are listed for sale. The for-sale group has roughly one-sixth the typical monthly revenue (\$187 vs. \$1,055) and less than one-quarter the growth rate (10% vs. 42%) compared to non-listed businesses. That indicates owners are generally selling stalled or weak businesses, not cashing out winners – listings are more a symptom of stagnation than a healthy exit market.

Made with GAMMA

Scene 5 – Pricing Multiples Vary Wildly

Asking prices correlate with revenue overall, but revenue multiples swing from under one year to over 300x monthly revenue. The most extreme multiples belong to listings earning almost nothing, where even a small price produces an enormous, misleading multiple. Therefore a single multiple is not a reliable shortcut – examine absolute revenue first before trusting multiples.

Revenue First

Look at absolute revenue before interpreting any multiple.

Multiples Mislead

Small revenues produce inflated multiples; quality isn't implied.

Scene 6 – B2B vs. B2C Trade-offs

B2B businesses earn about 5.7× more in typical monthly revenue than B2C (\$1,036 vs. \$181). Yet B2C is more numerous (401 vs. 255) and grows faster on average. The trade-off: B2B captures more revenue per customer (fewer, bigger checks, slower), while B2C requires scale (many smaller, faster-moving customers). Choosing which to build or buy is a decision about customer type and monetization strategy.

Scene 7 – Geography: Volume vs. Monetization

The U.S. accounts for the largest share of total revenue and its typical business earns the most. France ranks second by count but its typical business earns a fraction of the U.S. typical. India has even more businesses than France, yet its typical business earns nearly nothing. Volume does not equal monetization – lots of listings from a country can hide weak revenue performance.

United States

Largest revenue share; highest typical MRR.

France

Many listings but much lower typical MRR than U.S.

India

High listing volume but typical business earns close to nothing.

Scene 8 – AI Is Common, But Not Universally Winning

AI is the most common category and generates the most combined revenue, yet the typical AI business earns only \$446/month – modest compared to categories like Education or Analytics. The AI category's aggregate strength is carried by a few large winners above many small, unproven products. "AI" as a label is not a substitute for evidence of strong monetization.

The Bottom Line — How to Read This Market

Across every cut of the file the shape repeats: a handful of standout businesses hold most revenue and growth while the majority are small, flat, or being sold off. Over half of total revenue is behind listings with no category, and 129 anonymized “Stealth” businesses hold more than a quarter of revenue. Recommendations: don’t benchmark against averages (they’re distorted by outliers); use the median as the honest baseline; treat “for sale” as a warning flag; and view category or country breakdowns as partial until uncategorized revenue is identified. The dataset lacks answers for why 129 companies are anonymized or what drove extreme outliers — those require external investigation.
